Cosmological Tensor Perturbations in Brane Models

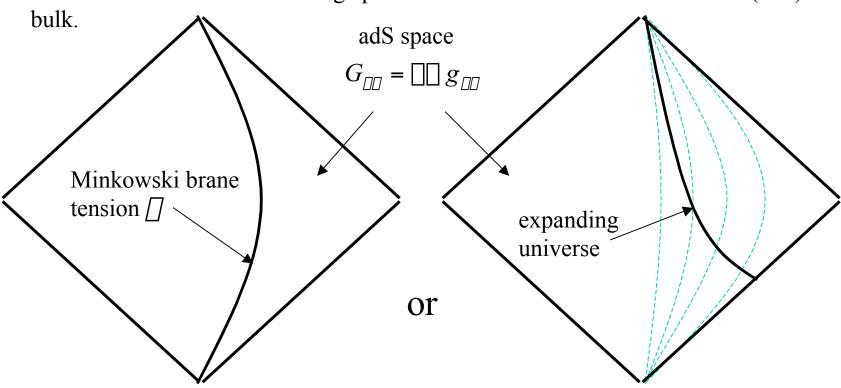

Andy Mennim

DAMTP, University of Cambridge

work in progress with R.A. Battye and C. van de Bruck

Randall-Sundrum model (RS2)

Our universe is a brane with large positive bare tension in an anti-de Sitter (adS)

Can calculate the following expression for the 4D Einstein tensor (Shiromizu et al.)

$$^{\scriptscriptstyle (4)}G_{\scriptscriptstyle \square\square} = \frac{1}{2} \square_{\scriptscriptstyle 5} \left(\square + \frac{1}{6} \square_{\scriptscriptstyle 5} \square^{\scriptscriptstyle 7} \right)^{\scriptscriptstyle 4)} g_{\scriptscriptstyle \square\square} + \frac{1}{6} \square_{\scriptscriptstyle 5}^{\scriptscriptstyle 2} \square T_{\scriptscriptstyle \square\square} + Q_{\scriptscriptstyle \square\square} \square^{\scriptscriptstyle (4)} C^{\scriptscriptstyle \square} \square_{\scriptscriptstyle \square} n_{\scriptscriptstyle \square} n^{\scriptscriptstyle \square}$$

- To get realistic gravity, we must tune the brane tension against the bulk cosmological constant, so as to make the first term vanish.
- The second term is the usual r.h.s. of the Einstein equations
- The third term represents terms quadratic in the energy-momentum.
- \triangleright In the last term, n is the unit vector normal to the brane and C is the Weyl tensor. This term represents brane-bulk gravitational interactions.

For a cosmological solution, get a modified Friedmann equation (pure adS bulk)

$$H^{2} + Ka^{\square 2} = \frac{1}{18} \prod_{5}^{2} \prod_{5} + \frac{1}{36} \prod_{5}^{2} \prod_{5}^{2}$$

Cosmological tensor perturbations

We will use Gaussian normal coordinates, where the brane is normal to one of the axes. The flat cosmological solution has a line element of the form

$$ds^{2} = n^{2} \left(\Box, \Box \right) d \Box^{2} + a^{2} \left(\Box, \Box \right) \left(\Box_{ij} + h_{ij} \right) dx^{i} dx^{j} + d \Box^{2}$$

Can solve for a and n in the cosmological background case (Binetruy et al.)

$$a(\square,\square) = a(\square,0) = \frac{\dot{a}(\square,\square)}{\square} \sinh(\square/l) = \frac{\dot{a}(\square,\square)}{\dot{a}(\square,0)} a(\square,0)$$

Here we have chosen a pure adS background and conformal time and *l* is the adS lengthscale.

Linearise the Einstein equations to get equation of motion for tensor perturbations

$$\ddot{h} + \begin{bmatrix} \frac{\dot{a}}{a} & \frac{\dot{n}}{n} \end{bmatrix} \dot{h} + k^2 \frac{n^2}{a^2} h = n^2 \begin{bmatrix} \frac{\dot{a}}{a} + \frac{n'}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{n}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{a}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{a}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{a}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{a}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{a}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{a}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{a}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{a}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{a}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{a}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{a}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{a}}{n} \end{bmatrix} h' + n^2 h \begin{bmatrix} \frac{\dot{a}}{a} + \frac{\dot{a}}{n} \end{bmatrix} h'$$

We have Fourier transformed in the x^i directions, with k^i the transform variable.

Can approximate the equation near to the brane, making it separable, writing

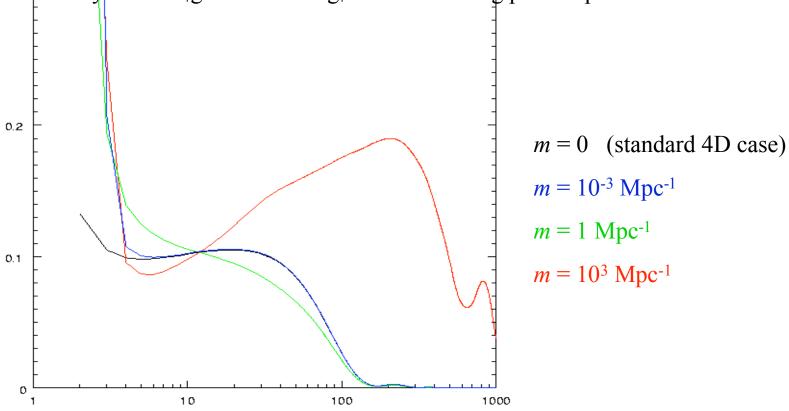

$$a(\square,\square) \square n(\square,\square) \square a(\square,0) e^{\square\square/l} \qquad h(\square,\square) = \square(\square)\square (\square)$$

Giving the following equation of motion for \square

$$\ddot{\Box} + 2\frac{\dot{a}}{a}\dot{\Box} + \left[k^2 + m^2a^2\right]\Box = 0$$

When m = 0, this looks like the standard equation for tensor perturbations in 4D cosmology. So we can gain a phenomenological understanding of tensor perturbations in brane-world models by setting m to some non-zero value, solving the equation

Conclusions

- A large amount of power is produced on large angular scales. Unfortunately, this will be difficult to measure due to cosmic variance.
- For large m values, we see a broad peak around 200 and considerably more power on smaller scales than in the usual 4D case.
- Scalar perturbations are more difficult, but watch this space!
- ➤ We need to know the relative abundances of the various modes for a particular theory, such as RS2, in order to rule it out.
- ➤ We see that higher dimensional theories and theories with massive gravity tend to break scale invariance in the power spectrum.
- This phenomenological method has the advantage of applying to a large class of models, not just RS2.
